```
##Using a Support Vector Regressor as our learning technique##
clf = svm.SVR(C=1, epsilon=0.2)
clf.fit(X_train_refined, y_train)
print ("MSE on the training set is:\n"), mean_squared_error(y_train, \
```

```
                                                clf.predict(X_train_refined))
        print ("MSE on the test set is:\n"), mean_squared_error(y_test, \
                                                clf.predict(X_test_refined))
```

```
MSE on the training set is:
12.0869268614
MSE on the test set is:
17.2529650053
```

```
In [227]: ##Using another learning technique (Random Forrest Regressor) on our data##
          rfr = RandomForestRegressor(n_estimators=10, random_state=0)
          rfr.fit(X_train_refined, y_train)
          print ("MSE on the training set is:\n"), mean_squared_error(y_train, \
                                                rfr.predict(X_train_refined))
          print ("MSE on the test set is:\n"), mean_squared_error(y_test, \
                                              rfr.predict(X_test_refined))
```

```
MSE on the training set is:
2.49144749533
MSE on the test set is:
15.9314309093
```

As we can see, both of these models tend to overfit the training set. Linear Regressors/K Nearest Neighbor/Neural Networks yield the same performance and all tend to overfit as well. We will try two different method to overcome overfitting.

```
1- We will try to use PCA to reduce the number of features
2- We will pick Random Forrest Regressor as our model and using the k-fold cross
validation technique fine tune the parameters of the SVR.
```

```
In [231]: ##Trying PCA and reducing the number of features and checking if the
          #performance on the test set improves##
          for n in [50,100,150,200]:
              pca = PCA(n_components=n)
              rfr.fit(pca.fit_transform(X_train_refined),y_train)
              print "With %d features, %f of variance is preserved and the MSE on\
              the test set is %f"%(n, pca.explained_variance_ratio_.sum(),\
              mean_squared_error(y_test, rfr.predict(pca.fit_transform(X_test_refined))))
```

```
With 50 features, 0.281870 of variance is preserved and the MSE on    the test set is 36.695022
With 100 features, 0.509171 of variance is preserved and the MSE on    the test set is 36.815525
With 150 features, 0.702820 of variance is preserved and the MSE on    the test set is 36.236900
With 200 features, 0.866501 of variance is preserved and the MSE on    the test set is 36.795260
```

We can see that almost all of the columns are containing significant amount of variance/data and even using 200 features we are still losing around 15% of the data. Also the performance of our model doesn't improve by using less features and it still overfit. So, next we try to fine tune the parameters of our RFR model using a 5-fold cross-validation

```
In [159]: ##trying different values for n_estimators parameters (number of trees in the forrest) and ev
          #using a 5-folded cross validation on the training set##
          est_list=[10,20,50,100,200]
          score={}
          for est in est_list:
              rfr = RandomForestRegressor(n_estimators=est, random_state=0)
              rfr.fit(X_train_refined, y_train)
              score[est]=cross_val_score(rfr, X_train_refined, y_train, cv=5).mean()
```

In [215]:
```
##finding the optimal value of n_estimators##
n_est=max(score.iteritems(), key=operator.itemgetter(1))[0]
print "the optimal value of n_estimators=%d"%(n_est)
```

```
the optimal value of n_estimators=200
```

In [232]:
```
##Using a Random Forest Regressor with the optimal C and epsilon parameters##
rfr = RandomForestRegressor(n_estimators=n_est, random_state=0)
rfr.fit(X_train_refined, y_train)
print ("score on the training set using optimal value of n_estimators is:\n"),\
mean_squared_error(y_train, rfr.predict(X_train_refined))
print ("score on the test set using optimal value of n_estimators is:\n"), \
mean_squared_error(y_test, rfr.predict(X_test_refined))
```

```
score on the training set using optimal value of n_estimators is:
1.67265451698
score on the test set using optimal value of n_estimators is:
13.7596595741
```

As we can see the performance improvement using a larger number of trees was marginal

In [233]:
```
##predicting the target on the given test set and writing the output into a text file##
final_test_DF=pd.read_csv('codetest_test.txt', delimiter='\t')
X_test_final_refined=data_refine(final_test_DF)
predictions=rfr.predict(X_test_final_refined)
f = open('predicted_target_test.txt', 'w')
for pre in predictions:
    f.writelines(str(pre)+'\n')
f.close()
```
